Missing / Outdated Content Gaps Report

Prepared from the supplied knowledge base and project files/code reviewed in this conversation | 10 November 2026

1. Executive summary

The supplied knowledge base contains 8 records. Based on the metadata and audit policy described in the supplied materials, 0 of the 8 records are currently eligible for production indexing. All 8 have pending approval and missing source-owner and last-verification metadata; privacy review is also pending. Two FAQ records contain a URL field, but the URL and its ownership have not been independently verified. No authorized user-feedback or review dataset was supplied, so no feedback records were processed or anonymized.

2. Missing or incomplete content and evidence

Gap	Evidence / impact	Required action
Formal source approval	All 8 KB records are marked pending approval; none established as approved.	Designated owner must review and explicitly approve each record; retain approval evidence.
Source owner	Owner is missing for all 8 KB records.	Assign the actual accountable source owner; do not infer an owner.
Last verified date	Missing for all 8 KB records.	Owner verifies accuracy against authoritative material and records ISO date.
Scheduled review date	No scheduled review dates supplied; code does not enforce review expiry.	Set a review cadence/date with the owner and implement expiry handling if required.
Authoritative URLs	Only faq-001 and faq-002 have a URL field; it is unverified. Other records have no URL.	Provide and verify official source locations and ownership; URL syntax alone is insufficient.
Feature guides	No approved feature-guide assets supplied or established.	Request current, owner-approved feature guides or document the absence.
Workflow documentation	faq-002 describes an expense-tracking workflow but workflow evidence is not verified.	Obtain the approved current workflow and reconcile the FAQ against it.
Feedback / reviews	No authorized feedback or review data supplied.	Obtain authorized feedback export or approved support-issue summaries; document authorization.
Privacy / anonymization	KB privacy review is pending; no PII scanning or anonymization implementation was identified in reviewed code.	Perform documented privacy review and anonymize feedback before any indexing.
Duplicate content	KB duplicate groups are empty, but semantic search code checks duplicate IDs, not duplicate content/aliases.	Run a content/alias similarity review and document merge/archive decisions.
Security claims	Security records are generic and not verified against product implementation.	Validate each product-specific claim with approved security documentation or implementation evidence.

3. Duplicate, outdated, and contradictory material handling

No confirmed outdated or contradictory product-source item was established from the supplied evidence. The knowledge-base audit metadata reports no duplicate content groups or aliases, but the reviewed semantic-search implementation only rejects duplicate IDs; it does not establish that duplicate content has been comprehensively detected. The uploaded rag_service_backup.py appears to duplicate rag_service.py and should be treated as a technical backup rather than a separate knowledge source. Do not permanently delete or describe any content as purged without a documented comparison and owner decision. Keep unapproved KB records quarantined from production indexing until their evidence is complete.

4. Feedback processing status and approved alternative

Status: blocked — no user feedback or review dataset was supplied. Records received: 0. Records processed: 0. Anonymization completed: none. This report does not claim that any personal information was scrubbed. If suitable review data is unavailable, the proposed alternative is a product-owner-authorized export of support-ticket issue summaries. The owner must confirm permitted use. Before knowledge-base use, remove direct and indirect identifiers (for example names, email addresses, phone numbers, account identifiers, transaction references and uniquely identifying free text), retain only necessary issue and resolution information, and obtain privacy approval.

5. Implementation review observations

• The reviewed RAG service filters for verified, approved, indexing-eligible documents with complete audit metadata and provides a safe fallback when no eligible source is available.

• The reviewed semantic-search code validates required metadata, URL syntax, ISO date format, privacy_review approval, embedding shape and duplicate IDs.

• The reviewed code does not enforce scheduled review dates/expiry, verify that URLs belong to an authoritative domain, scan/anonymize PII, or detect duplicate content/aliases.

• Five test cases were reviewed in the supplied test code. They cover pending and approved metadata, missing owner, invalid URL/date, and duplicate IDs. They were not executed as part of this document preparation.

• The historical REPORT.md states that 11 tests passed and reports 8 KB documents, 16 blocking findings and 0 production-eligible documents. These are historical report claims and were not rerun here.

6. Recommended closure sequence

1. Obtain the designated owner for each source record.

2. Collect official URLs and source documents for every FAQ, workflow, feature guide and security claim.

3. Have owners verify content, record last-verified dates, approve content and privacy review, and assign scheduled review dates.

4. Obtain an authorized feedback source or formally record that no suitable feedback source is available; anonymize before use.

5. Review duplicate content and aliases; record each merge, archive or retention decision.

6. Re-run the audit and tests, including privacy, scheduled-review expiry and duplicate-content cases, before enabling production indexing.

Audit limitation

This deliverable is based only on the materials supplied and reviewed in the conversation. It is a documentation of evidence and gaps, not an independent confirmation of the live HisabDo product, official website ownership, deployed security controls, or production data. Missing fields are deliberately marked as not provided rather than guessed.
